CASE STUDY

A school canteen platform that took the allergen risk out of lunch

Allergen safety, meal pre-ordering and billing for an international school, built from scratch. A daily process that needed 7+ staff now runs with 2.

My role: product manager | 5 years in production | About 2,500 users | One school

The problem

An international school served lunch through a manual process: spreadsheets and hundreds of physical tokens handed out and collected every day. It did not control the one thing that mattered most, students coming into contact with food allergens. That was a liability risk for the school, and no product on the market solved it.

What I did

I was the school's IT manager, and I took ownership of the problem as product manager. I wrote the requirements from scratch, designed the application, sourced a remote team of four developers and drove the build from first line to go-live.

Design decisions that came from watching the real environment

Barcode readers, not cameras

Dedicated barcode readers at the serving counter. Camera scanning fails at volume once a queue of students builds up.

Allergens as images

Serving staff see allergens as images, because many do not share a language with the students. Allergens are also filtered when a parent makes the reservation.

A kitchen display you never touch

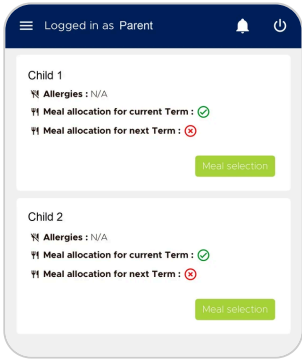

The kitchen tablet only displays, so staff keep their hands free. This was designed during COVID.

What it looks like

Parents pre-order meals in a mobile app and pay online by card. Each child's allergies and meal allocation sit on one screen, so a mistake is hard to make and easy to see.

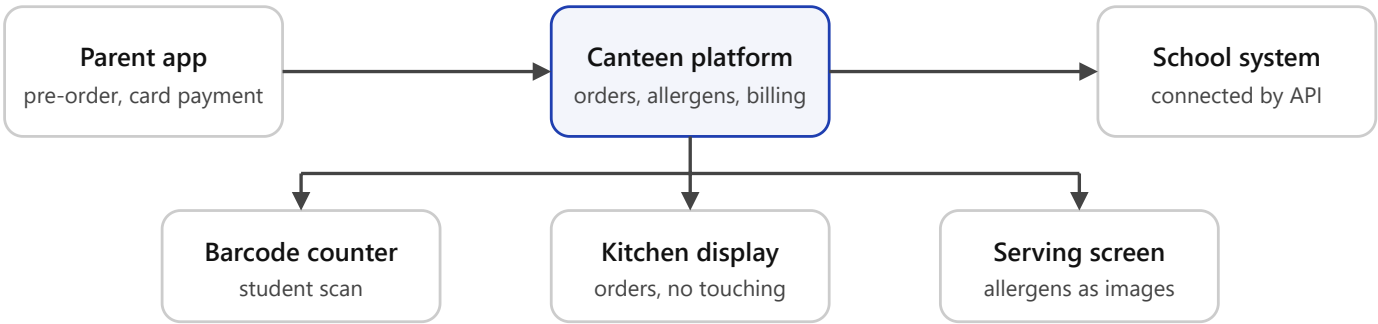

The allergen icons below are the ones the app uses: pictures instead of words.

Parent app home screen, with demo data.

How it works

The result

7+ to 2
staff needed each day for the meal process

5 years
in production

About 2,500
users: students and their parents

- ✓ The allergen risk at the point of service is effectively removed.
- ✓ The spreadsheets and hundreds of physical tokens are gone.

Where it is now

The platform is being modernized with AI coding tools: .NET 4.5 to .NET 10 and a React upgrade across several major versions, with the interface and functions redesigned as part of it.

Terms: school canteen management, allergen management, mobile pre-ordering, barcode access, online card payments, API integration, .NET, React Native, legacy modernization.
